Tutorial 08

Friday, May 21, 2010 (Time : 10¹⁵ – 11⁰⁰, Room : HS 14)

- 28** Consider the macro element $M = (-1, 1) \times (-1, 1)$, consisting of four squares T_1, \dots, T_4 and nine gridpoints x_1, \dots, x_9 :

The edges of M are denoted $S_1 = [x_3, x_9]$, $S_2 = [x_9, x_7]$, $S_3 = [x_7, x_1]$, $S_4 = [x_1, x_3]$, the union over all squares in $\{T_1, \dots, T_4\}$ that contain the grid point x_i is denoted Δ_i , and the area of Δ_i is denoted $|\Delta_i|$. Show, that for each function in $C(\overline{M})$ there exists a unique Function $v_h = \Pi_h v \in C(\overline{M})$ which is bilinear (=quadrilinear) on each piece in $\{T_1, \dots, T_4\}$, and satisfies

$$\forall i \in \{1, 3, 5, 7, 9\} : v_h(x_i) = \frac{1}{|\Delta_i|} \int_{\Delta_i} v \, dx, \quad \forall j \in \{1, 2, 3, 4\} : \int_{S_j} v_h \, ds = \int_{S_j} v \, ds.$$

For $i \in \{1, \dots, 9\}$, let $\varphi^{(i)}$ be the piecewise bilinear nodal ansatz functions which satisfies the relation $\varphi^{(i)}(x_j) = \delta_{ij}$. The function v_h , as defined above, can be written as

$$v_h(x) = \sum_{i=1}^9 \alpha_i \varphi^{(i)}(x). \quad (4.57)$$

Calculate the coefficients α_i explicitly!

- 29** Consider the assumptions and definitions in Example 28. Show, that there exists a constant $c_F > 0$, such that for all $v \in C^1(\overline{M})$ there holds $\|\Pi_h v\|_{H^1(M)} \leq c_F \|v\|_{H^1(M)}$. *Hint:* Use the representation (4.57). The coefficients α_i can be written in terms of $\int_{\Delta_i} v \, dx$ and $\int_{S_i} v \, ds$. Use Cauchy's inequality and identities like

$$\int_{S_1} v \, ds = \int_{\partial M} (v t, n)_{l_2} \, ds = \int_M \operatorname{div}(v t) \, dx, \quad \text{where} \quad t(x, y) = \begin{pmatrix} (x+1)/2 \\ 0 \end{pmatrix}.$$

- 30** Consider the assumptions and definitions in Example 28. Show, that there exists a constant $C > 0$ such that

$$\|v_h - v\|_{H^1(M)} \leq C \|v\|_{H^1(M)} \quad \forall v \in C^1(\overline{M}).$$

Hint: Show, that $v_h - v = \Pi_h v - v = \Pi_h(v + c) - (v + c)$ holds for any arbitrary constant function c . With Example 29 one obtains $\|v_h - v\|_{H^1(M)} \leq \tilde{C} \|v + c\|_{H^1(M)}$. In order to estimate $\|v + c\|_{H^1(M)}$ from above, use Poincaré's inequality

$$\|w\|_{L_2(M)}^2 \leq c_P^2 \left(\left(\int_M w \, dx \right)^2 + |w|_{H^1(M)}^2 \right)$$

for $w = v + c$, where c is chosen properly.

- 31*** Consider the assumptions and definitions in Example 28 and replace $M = (-1, 1) \times (-1, 1)$ by $M_h = (-h, h) \times (-h, h)$, where $h \in (0, 1]$. Show, that there exists a constant $c > 0$ independent of h ($c \neq c(h)$) such that

$$\|v_h\|_{H^1(M_h)} \leq c \|v\|_{H^1(M_h)} \quad \forall v \in C^1(\overline{M_h}) \quad \forall h \in (0, 1].$$

Hint: Use $\|v_h\| \leq \|v_h - v\| + \|v\|$ and (after a proper transformation of variables) the estimate of Example 30.
